Executive Summary

The new political momentum generated by the European Green Deal and the legally binding objective of climate neutrality by 2050 have given carbon capture and storage (CCS) and carbon capture and utilisation (CCU) strengthened and growing interest from policy makers and industrial stakeholders. CCS and CCU will support Europe's pathway to achieve climate neutrality, enabling a cost-efficient pathway for energy-intensive industries and power plants, safeguarding jobs in core sectors of the EU economy while creating others along the CCS/CCU value chain and preserving industrial competitiveness.

In the Impact Assessment on 'Stepping up Europe's 2030 climate ambition', the European Commission found that it is critical that CCS and CCU are deployed and tested at the industrial scale during this decade. Identifying key enablers and existing barriers for the scale up of CCS and CCU is thus important to create the right economic conditions and a favourable policy framework to enable investments in CCS and CCU.

This report identifies and discusses four categories of enablers and hurdles: technical, policy and regulatory, funding and business models and social acceptance, drawing from the expertise of the first commercial CCS and CCU projects that are currently being developed in Europe. These projects will provide a clear signal for industries to capture CO₂ at industrial plants and the backbone infrastructure to which the next generation of CCS and CCU projects will be able to connect, creating Europe-wide CO₂ transport and storage and giving access for CO₂ emitters in industrial hubs to safe storage sites or utilisation networks.

As part of the European Green Deal workplan, the European Commission has announced new initiatives – such as the European Climate Law, the Hydrogen strategy, the Industrial strategy – and intends to revise existing pieces of legislation, such as the EU ETS directive and TEN-E regulation. All these initiatives are key to ensure that more CCS and CCU projects are deployed in Europe, overcoming current barriers and securing more announcements such as the Longship project and funding awarded through the Connecting Europe Facility for Energy (CEF) programme to European CCS and CCU projects (Porthos, Athos, Antwerp CO₂, Acorn Sapling, Ervia).

To support these recent positive developments and encourage more, R&I activities should be continued to address technical challenges along the value-chain, reduce the costs of the

technologies and improve efficiency. Social acceptance challenges remain and will require the action of a wide group of societal stakeholders to be addressed. Local administrators, NGOs, academia, and other economic stakeholders play a central role in increasing the awareness around CCS and CCU and facilitating an informed debate around it.

To summarise, CCS and CCU can support the EU's decarbonisation pathway, delivering climate change mitigation and circularity, carbon dioxide removals and early, large-scale volumes of clean hydrogen for industry and homes. Testing and deploying these technologies at scale during the 2020s will be crucial to Europe's success in achieving net-zero by 2050.

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 842214

Introduction

The CCUS SET-Plan, IWG9

The European Strategic Energy Technology Plan (SET-Plan) aims to accelerate the deployment of low-carbon technologies, improve new technologies and bring down costs by coordinating national research efforts. The SET-Plan brings together EU countries, the European Commission, industries and research institutions.

The SET-Plan defined ten priority areas, covering a wide range of sectors including CCUS, wind, solar, geothermal, renewable heating and cooling, biofuels, etc. All priority areas have a dedicated working group.

The Implementation Working Group 9 (IWG 9) has been established to help the progress of Research and Innovation (R&I) activities required to achieve the 2020 targets for CCS and CCU agreed by the European Commission, SET-Plan countries and industry. R&I activities are outlined in the [CCS and CCU Implementation Plan](#).

The IWG 9 consists of five thematic subgroups. Subgroups are currently in the process of being populated by experts in relevant areas.

The task at hand

The aim for this report is to:

- identify the key enablers and the common critical barriers impacting the development and deployment of large-scale CCS and CCU projects
- assess why the barriers appear and how they can be avoided
- highlight how the enablers can be strengthened and shared with the whole European CCS and CCU project community.

The enablers and barriers have been divided into the following categories:

- Technical
- Policy and regulation
- Funding and business models
- Public acceptance/perception

The work is carried out by CCSA in cooperation with CO2VE. The basis for the report is presentations and discussions at seminars between the IWG9 and CCUS Projects Network.

CONTACT DETAILS

This report has been discussed in the different IWG9 subgroups and circulated to the SET-Plan CCS and CCU community for comments.

The political context

The European Green Deal, Europe's new growth strategy, set the legally binding target of net-zero greenhouse gas emissions by 2050 in the European Climate Law. All economic sectors and member states will need to make strong efforts to reduce greenhouse gas emissions. This means that all low-carbon technologies with a scientifically proven role in achieving climate change mitigation should be developed and deployed. In this context, carbon capture technologies have been highlighted as necessary in order for Europe to reach climate-neutrality in all credible Integrated Assessment Models and scenarios (including the 1.5 degrees IPCC report and the European Commission Clean Planet for all, long-term strategy).

CCS/CCU status in Europe

In the mid-1990s, the Norwegian site of Sleipner – the world's first large-scale, dedicated CO₂ geological storage facility – began operation, storing CO₂ emissions from natural gas processing. According to a 2019 report on the global status of CCS, on the Norwegian continental shelf, Sleipner CO₂ storage and Snøhvit CO₂ storage facilities have cumulatively captured and stored around 22 million tonnes of CO₂¹.

Defined as a 'breakthrough technology' and identified as a priority area in the European Green Deal communication, the development of CCS and CCU gained positive political momentum at the end of 2019, which led to further developments and announcements in 2020.

In May 2020, the Northern Lights partners took their Final Investment Decision (FID) and received approval from the EFTA Surveillance Authority (ESA), with only a final investment decision pending from the Norwegian government. In October, the PORTHOS project in the Netherlands has been awarded CEF funding, which will contribute to the overall needed expenditure.

In other countries, around the North Sea Basin, large-scale CCS projects are also well underway. The 4th Projects of Common Interest list now has five CO₂ cross-border projects, with two projects, Athos and PORTHOS, in the Netherlands, Acorn Sapling in the UK, ERVIA in Ireland, and Northern Lights in Norway completing the list. The provisional

¹ https://www.globalccsinstitute.com/wp-content/uploads/2019/12/GCC_GLOBAL_STATUS_REPORT_2019.pdf

CONTACT DETAILS

implementation of the amendment to Article 6 of the London Protocol of October 2019 removed the biggest legal barrier for these projects by allowing CO₂ to be exported for the purpose of offshore storage.

In Iceland, the Carbfix project has advanced carbon capture and mineralisation (CCM) to TRL9 where CO₂ from geothermal power plants is captured and permanently stored in basalts as solid minerals. Carbfix and Climeworks will start operating the first industrial scale direct air capture and storage (DACCS) chain in early 2021 and a new onshore storage site is in preparation that can receive CO₂ transported by ship.

Belgium and Sweden are also among the countries that have shown interest in the technology and have taken initial steps. Belgium's activity focuses in the area of the Port of Antwerp, where industries are coming together and evaluating the possibility to connect to the CO₂ transport and storage infrastructure in the Port of Rotterdam area and/or Northern Lights. Sweden, who has recently ratified the amendment to Article 6 of the London Protocol, has several interesting projects, including Bio-CCS by Stockholm Exergi and CCS Lysekil, both linked to the Norwegian Northern Lights project.

CCU is a new industry allowing the carbon cycle to be closed by reusing emissions for the production of fuels, chemicals, or materials. In recent years, several projects have demonstrated the technologies at high TRL levels (e.g. STORE&GO, MefCO₂, Align-CCUS), and small commercial-scale plants already exist (George Olah Plant producing methanol from CO₂ in Iceland). Further commercial projects have been announced in the short term (e.g. Port of Antwerp, GreenLab, Norsk e-fuel) with the aim to achieve the commercialisation of tens of kilotonnes of product annually.

Preliminary analysis² of the national energy and climate plans (NECPs) suggests that other countries are leading R&I activities or assessing the feasibility of CCS and CCU for their countries. From an early assessment, the next developments in CCS and CCU can be expected in the Netherlands (Rotterdam and Amsterdam), Norway, the UK, Ireland, and Belgium – the area of Port of Antwerp, France (Dunkerque) and Italy (Ravenna).

CONTACT DETAILS

Key enablers and hurdles impacting CCS and CCU deployment

At present, four main areas have been identified as hurdles for CCS and CCU large-scale deployment. The following chapters aim to address the barriers and propose ways forward:

- Technical barriers
- Policy and regulation
- Business models and funding
- Public acceptance / perception

Technical barriers

While CCS and CCU are often described as low-carbon technologies with high potential for reducing GHG emissions in industrial and energy sectors, technical barriers for large-scale deployment still exist and are yet to be addressed. To better identify these barriers, there is a need to look at the different parts of the CCS and CCU value chain: CO₂ capture, transport, storage, and utilisation.

Continued R&I is crucial. The ongoing and soon to start CCS and CCU projects will identify new challenges/barriers that can be solved by undertaking R&I in parallel with large-scale activities. An iterative process is needed where R&I projects address specific challenges and barriers, with the results then implemented in large-scale projects.

CO₂ capture

Capture technologies can remove >95% of the CO₂ from flue gasses or industrial processes, and waste gas streams, which would otherwise be emitted to the atmosphere³. These technologies can decarbonise power generation, energy-intensive industries, and large-scale hydrogen production. Importantly, for sectors such as iron and steel, cement, and chemicals production, the manufacturing processes produce CO₂ as a by-product of chemical reactions (not combustion), and CCS is one of the very few solutions to cost effectively address these ‘process emissions’ and enable these industries to decarbonise.

The number of different capture technologies and suppliers that are available has increased steadily, which means that the general technical availability is no longer a hurdle in itself for both industrial and power applications. It is critical that R&I activities receive enough

³ IEAGHG, [Towards Net-zero Emissions](#), 2019.

CONTACT DETAILS

support to keep reducing the costs of CO₂ capture for investors and boost technological progress. In this respect, it is clear that the next developments of capture technologies will have a focus on increasing their efficiency, i.e. increasing capture rates.

Currently, challenges and barriers for CO₂ capture can be identified in two main areas:

- Reducing costs of CO₂ capture at industrial sites and power plants
- Increasing the capture rate of capture technologies.

CO₂ transport

Captured CO₂ is then transported to a geological storage site or a utilisation facility. Transportation can occur/can be facilitated in a network of pipelines, using shipping or other modalities (rail freight, truck, etc.). Transportation of CO₂ is a well understood process, that has been taking place in Norway and North America for several decades. CO₂ transport by pipeline has characterised existing CCS/CCUS projects (Snøhvit, Sleipner), but CO₂ transport by ship will be crucial to enable the five PCIs to become operational.

There is a need to address matters such as the technical specifications for CO₂ streams, CO₂ purity, CO₂ flows, and the design of pipelines, ships, and other parts of the transport value chain – especially when retrofitted for low-carbon gases and CO₂ transport. Many of the technical challenges related to CO₂ transport are further outlined in a recent ZEP report on CO₂ transport. Further work is needed regarding whether or not the difference in quality requirements of captured CO₂ for utilisation influences the CO₂ transport specifications.

The development of CO₂ transport and storage infrastructure networks to connect industrial ‘clusters’ with other CO₂ capture sites and finally to CO₂ storage and utilisation sites and across international borders is key to progress CCS and CCU in Europe. Such CO₂ transport infrastructure can serve as a backbone for industrial decarbonisation, delivering negative emissions and enabling the delivery of early, large quantities of clean hydrogen from reformed natural gas with CCS. A central requirement for the efficient, safe design and operation of CO₂ pipeline transportation networks is the accurate transient flow modelling of fluid phase and composition of the CO₂-rich mixture along the pipeline network and at the point of injection into the storage site. Further study is needed to assess the quality of CO₂ streams, as well as CO₂ density and pressure, ensuring ongoing monitoring of CO₂ flows and pipeline safety during operations. Further work should also address the combination of scenarios relating to changes in future energy supply mix and industrial landscapes alongside the development of CO₂ pipeline transport networks.

CONTACT DETAILS

European, cross-border CO₂ transport and storage infrastructure would also rely on transport modalities other than pipeline. It is critical that other modes of CO₂ transport, like ship, truck, or barge, are studied and thoroughly understood to enable upcoming large-scale CCS projects, including where these modalities may interact in a network.

When kicking off a CO₂ infrastructure project, it is important to consider that the different parts of a CCS/CCUS value chain/CO₂ infrastructure – capture, transport, storage, utilisation – will most likely be developed and realised at different times, raising the counterparty risk in the value chain for potential investors.

Facilitating the technical and commercial operation of such networks under clear legal frameworks, along with investable developed business models and regulatory structures, needs to be the focus of further CO₂ transportation development, as well as the limited ratification of the amendment to the London Protocol, enabling the export of CO₂ between countries, will need to be addressed to ensure the large-scale development of CCS and CCU projects in Europe.

A recent report, “A Trans-European CO₂ Transportation Infrastructure for CCUS: Opportunities & Challenges”⁴, further outlines the challenges related to CO₂ transport.

CO₂ storage

CO₂ geological storage is a safe and mature technology ready for broad implementation, as evidenced by over twenty years of successful storage offshore in Norway, combined with more recent onshore storage in Canada and the USA. In Europe, CCS benefits from a clear set of regulations and requirements under the 2009 EU CO₂ Storage Directive that ensure the identification of appropriate storage sites and the safety of subsequent operation⁵. The CO₂ is injected into the microscopic pore space within storage formations (such as depleted oil and gas fields or saline aquifers), where it becomes permanently trapped.

The EU CCS Directive⁶ is a robust regulatory framework, which ensures that CO₂ storage activities are undertaken to the highest safety standards.

Challenges associated with CO₂ storage in Europe are further outlined hereafter:

- The matter of CO₂ liability risks for long-term storage needs further clarification. It is particularly important to assess how private investors and governments should share long-term CO₂ storage risks.

⁴ Zero Emissions Platform, 2020, A Trans-European CO₂ Transportation Infrastructure for CCUS: Opportunities & Challenges. Available at <https://zeroemissionsplatform.eu/a-trans-european-co2-transportation-infrastructure-for-ccus-opportunities-challenges/>

⁶ European Commission, [Directive on geological storage of carbon dioxide](#), 2009

CONTACT DETAILS

- In order to deliver large-scale decarbonisation and reach climate neutrality by 2050, there is a paramount need to invest, support and further develop CO₂ storage by incentivising storage appraisal at both offshore and onshore sites. The development of a European storage atlas, with the use of artificial intelligence and big data, is also an important milestone and target of the SET-Plan.
- As highlighted in previous engagements, it is important that Europe makes the most out of funding instruments for low-carbon technologies, such as the Innovation Fund. Facilitating the individual applications of projects aiming to develop CO₂ storage offshore or onshore should be considered under the Innovation Fund. This would effectively set the basis for the backbone of European CO₂ infrastructure, to which CO₂ emitters from across Europe can connect.
- Storage appraisal activities should also look at the development of CO₂ storage sites for small emitters.

CO₂ utilisation

Captured CO₂ can also be used as a feedstock for a variety of industrial purposes (e.g. methanol and synthetic fuel production, in building materials, used as solvents, or in greenhouses). An alternative to the permanent storage of CO₂ is CCU (such as the production of synthetic fuels). The CO₂ abatement potential of CCU technologies depends on the origin of CO₂ (fossil, biogenic, or directly captured from the air), the emissions associated with the process used, and any possible emissions from use of the final product. Therefore, it is of key importance to properly monitor, account, and report the full lifecycle of the CO₂ to correctly reflect the actual carbon footprint.

CCU comprises technologies at different levels of maturity and process complexity. From a technical point of view, a more rapid deployment of CCU technologies can be achieved through the large-scale development of:

- Novel and cost-effective materials (membranes, adsorbents, absorbents) with high durability and recyclability for capture that is performant and tailored to the purity requirements of the subsequent use.
- New catalysts and materials for energy- and resource-efficient conversion technologies into fuels and chemicals (electrochemical, photoelectrochemical, thermochemical, biological).
- Integrated systems that can combine capture and conversion in one reactor, addressing the need for input synchronisation during continuous operation (e.g. CO₂, renewable energy availability).

CONTACT DETAILS

At the same time, logistical considerations are also important for the development of certain CCU pathways (e.g. accommodating large volumes of waste fractions for CO₂ mineralisation due to limited CO₂ uptake rate, ensuring symbiotic infrastructure among CO₂ emitters and CO₂ converters in clusters of concentrated industrial activity).

Currently, an increasing number of LCA studies regarding the environmental benefits of CCU are being published. It will be crucial to systematically follow this up to provide evidence of the mitigation potential of CCU technologies.

Policy and regulation

A favourable policy and regulatory framework is key for the large-scale development of CCS and CCU technologies and the kick-off of European CCS and CCU projects in this decade. While the mitigation role of CCS is demonstrated and acknowledged, the political support for the technology has been proven to not be sufficient, causing delays and proving to be a major barrier for large-scale CCS projects in the early 2000s.

It is crucial that the European Union sends a strong message in support of CCS and CCU development, giving predictability to companies for long-term investments and ensuring that a coordinated policy framework is in place to facilitate the uptake of CCS and CCU technologies across Europe. In this respect, raising awareness with policymakers about the benefits and the challenges of CCS and CCU is vital.

At the same time, it is important to raise awareness with industrial stakeholders, especially those for which CCS and CCU technologies will prove to be the lowest-cost route to large-scale decarbonisation. For industries such as cement, lime and steel – where electrification will only have limited potential – CO₂ transport and storage infrastructure will not only deliver real decarbonisation, but it will also protect existing jobs, industrial manufacturing, and income; and there is a possibility for CCU to allow them to become circular by reusing their emissions.

Referring to conclusions from the most credible Integrated Assessment Modellings, in order to reach climate neutrality, it will not be enough with climate mitigation technologies – we also need Carbon Dioxide Removals (CDR). To stimulate the development and deployment of CDR, there is a need to deploy CCS and also introduce clear functioning incentives for CDR. As an example, if you are already producing energy based on biomass, it must be economically feasible and attractive to invest in CCS to create CDR. In this context, it is of key importance to properly monitor, report, and account for the emissions and removals of CO₂ associated with CCS and CCU to correctly reflect their actual carbon footprint. A robust carbon removal certification mechanism (as announced in the Circular

CONTACT DETAILS

Economy Action Plan) will allow tracking of the CO₂ fluxes, especially for CCU technologies that are not yet commercially mature. Such certifications can allow regulatory incentives for market uptake of CCU products, which may be slow in the short term due to high investment costs.

Legal challenges that are specifically highlighted within the context of networks refer to cross-border transport of CO₂ and the coordination of CO₂ streams from different sources. Since October 2019, parties to the London Protocol that wish to participate in a cross-border CO₂ network for (also) offshore CCS can now unilaterally declare the provisional application of the 2009 amendment and enter into respective agreements with other parties, allowing the export of CO₂ for offshore storage.

More coordination at EU level is needed to address existing differences in legal requirements with regards to the construction and characteristics of pipelines for cross-border pipeline projects, as well as clear guidelines regarding specific requirements for CO₂ pipelines.

At EU level, the European Commission's Directive 2009/31/EC ensures third-party access to CO₂ networks, following precise CO₂ specifications with the aim to guarantee access and compatibility in the network. The EU will still need to coordinate this network by issuing guidelines on the requirements of CO₂ streams.

Political support for the five cross-border CO₂ Projects of Common Interest⁷ (PCI) is vital. These projects are on the right track to become operational before 2025. A solid policy framework providing a degree of predictability for long-term investments should be a priority for European policymakers. CO₂ infrastructure projects call for European legislators to extend the scope of existing legislation – such as the TEN-E regulation and EU ETS directive – to prepare for the rollout of CO₂ and clean hydrogen infrastructure.

As indicated in the European Taxonomy for Sustainable Finance (Taxonomy), all modes of CO₂ transportation to permanent geological storage – pipeline, ship, barge, train, truck – are allowed. This outcome is critical and should be preserved and reflected in revised TEN-E and EU ETS regulation, as it will allow near-ready CO₂ transport and storage projects to be realised and to create opportunities for numerous CO₂ emitters throughout the entire EU area to have access to low-cost decarbonisation pathways.

⁷ European Commission, "[Technical Information on Projects of Common Interest](#)", 2020

CONTACT DETAILS

Another challenge is captured CO₂ from biogenic sources and how to store it. There are no incentives for CDR under the EU ETS.

While both CCS and CCU are included in the proposed regulation on the establishment of a framework to facilitate sustainable investment⁸, CCS is defined as an eligible technology in the Taxonomy while CCU is not yet included. This is due to a lack of evidence regarding its mitigation effect and the issue has been forwarded to the Taxonomy Platform. The Zero Emissions Platform (ZEP) is working on input to the Taxonomy Platform regarding screening criteria, which can accompany evidence on mitigation effect and provide a basis for a new decision regarding the inclusion of CCU.

The Taxonomy also currently disqualifies all CO₂ transport assets that are connected to CCU. This is a very important barrier to eliminate⁹.

There is still not enough political acknowledgement of the role of CCS and CCU for the decarbonisation of energy and industry sectors, especially energy-intensive industrial value chains. The National Energy and Climate Plans and long-term strategies of European member states provide an indication of national attitudes towards the technologies. An early assessment shows that 12 countries have included the development of R&D activities around CCS in their NECPs, while four countries have included the development of a CCS strategy and large-scale projects by 2030.

As part of the European Green Deal, several policy initiatives and revisions have been announced that will be relevant for CCS and CCU and others will be presented. Overall, the political momentum for low-carbon technologies created by the European Green Deal creates a unique opportunity to enable a supportive policy and legal framework for CCS and CCU in the European Union.

The provisional implementation to the London Protocol in force since October 2019 has removed the legal barrier to export CO₂ for offshore storage. However, the solution is a provisional implementation and it would be a strong political signal if those member states, that have not yet done so, will ratify the amendment to Article 6 and reduce the gap to the threshold for the formal enforcement of the amendment.

A legal storage challenge concerns the lack of general regulation for depleted oil or gas fields to do a proper assessment of CO₂ storage potential at decommissioning (however, this is more of a national issue).

⁸ Article 6, COM(2018) 353

⁹ Zero Emissions Platform, 2020, Future-proofing the Taxonomy regulation regarding CO₂ transport infrastructure. Available at <https://zeroemissionsplatform.eu/future-proofing-the-taxonomy-regulation-regarding-co2-transport-infrastructure/>

CONTACT DETAILS

As far as CCU is concerned, this is the opportunity for legislative packages that are crucial for rapid deployment to be more supportive. For example, the announced revision of REDII should take into account industrial realities as far as the conditions for renewability, additionality, and temporal and geographical correlation of electricity use in CCU. Furthermore, the ETS should also be expanded to enable emitters not to surrender allowances from the moment that CO₂ is further reused in CCU applications. For example, mineralisation of CO₂ into a construction product is sequestering CO₂ in a way that is equivalent to geological storage and it is important to be recognised as such also in the ETS.

Business models and funding

The biggest hurdle for CCS and CCU deployment is the market failure that prevents the creation of viable business cases.

Investing in shared CO₂ transport and storage infrastructure is the ultimate European project, and it represents a strategic and instrumental policy decision to preserve Europe's welfare and to make European society future-proof for a climate-neutral economy. As several CO₂ capture projects are near-ready for large-scale deployment, European CO₂ transport and storage infrastructure would connect CO₂ emitters (industrial hubs and power plants) to storage sites and enable the extensive decarbonisation that will be needed to meet the climate neutrality target. Timely development of this infrastructure is crucial and will also enable industry to take a proactive role in the discussions around 2030 and 2050 climate targets.

Funding mechanisms are a vital element to unlock private investments in CCS and CCU large-scale projects. The European Union is currently offering funding opportunities through the R&I programme Horizon Europe, the Connecting Europe Facility and the EU ETS Innovation Fund. Some countries – e.g. the Netherlands, Norway, and the UK – are also studying/introducing national funding schemes (subsidies, carbon tax, incentives, etc.) to support the development of early, large-scale CCS projects.

The cross-value chain risks (counterparty risks) that are inherent between the different parts along any CCS/CCU value chain (capture – transport – utilisation/storage) remain a high business risk. No compensation mechanisms are currently previewed by the European Commission to mitigate the business exposure for any party in a CCS/CCU value chain in the event one party is underperforming, especially under the Innovation Fund. This is

CONTACT DETAILS

preventing the optimal use of funding to create shared transport and storage infrastructure.

In the absence of a “functional” (global) carbon price (minimum EUR50-60/tCO₂), investment in CCS will have no market driven business case and will largely depend on public funding and policy incentives (e.g. to purchase zero-carbon products, such as clean steel or cement). It is therefore crucial to fund R&I activities to develop an infrastructure backbone and reduce costs. Public support and incentives will be necessary in this case to create and maintain the market and reduce high initial investment costs for upscaling and reaching commercial maturity.

CCU is facing similar issues despite the fact that the business case exists with the production of a marketable product that can be a substitute for a conventional one.

Necessary steps to support the development of the European CCS sector are:

Recognition and political support for common European CO₂ infrastructure – the EU has a key enabling role to ensure that European industry has access to CO₂ transport and storage and utilisation: shared CO₂ infrastructure can deliver clean, competitive industrial sectors, clean and flexible energy systems, an early, large-scale clean hydrogen economy, and negative emissions.

An enabling policy framework, making it economically feasible for companies to invest in the whole value chain of CCS and CCU:

- In the short term, incentives to support timely large-scale deployment of all parts along the CCS and CCU value chain – support for both CAPEX and OPEX.
- In order to reach all European emitters, CO₂ transportation modalities other than pipeline – such as ship, rail, or truck – must be included in all relevant legislation.
- An Innovation Fund that can support both part of and the whole CCS and CCU value chain including the development of hubs.

It is imperative that EU and national funding programs are coherent and coordinated.

A functional and relevant carbon price – a robust EU Emissions Trading System – is expected to support investment once the technology is more mature (similar to other mature technologies). The development of a market for low-carbon/climate-neutral products is also foreseen as important.

The current funding instruments need to be *deployed in pursuit of the European Green Deal and the green recovery*. Policies and legislation on EU, regional and national level (also using

CONTACT DETAILS

the NECPs as a tool), as well as funding programs (Horizon Europe, SET-Plan targets and activities, etc.) and instruments, must be assessed and revised based on the new EU Climate Law and updated targets.

Social challenges

In general, there is limited awareness of the value and benefit from CCS and CCU technology. There is a great need to clearly describe the value and also highlight how CCS and CCU technologies affect the everyday life of EU citizens and consumers' choices – both regarding why these technologies are necessary and the applications that can be chosen from; everything from hydrogen for transport and heating to specific low-carbon products. It is necessary to help both policymakers and citizens/consumers to see and understand these values and benefits.

Bringing together policymakers at local, regional, national and EU level with companies and other societal actors, such as trade unions and environmental NGOs, will be a key driver for the development of CCS and CCU projects and raise awareness about their climate and economic benefits. Education of pupils at schools and visits to CCS/CCU facilities should be encouraged as a way to inform and promote their interest for the technology and develop increased awareness.

At European level, the European Commission has a good opportunity with initiatives such as the upcoming CCUS Annual Forum, which was recently announced as part of the Strategy for Energy System Integration. This opportunity can bring together stakeholders from different groups to learn more about CCS and CCU technologies and highlight the challenges that they encounter and the value and benefits that CCS and CCU can bring.

Conclusions

The dramatically changing political landscape of the European Green Deal and the EU ambition to reach net-zero GHG emissions by 2050 requires immediate action. All economic sectors will need to contribute to reach the target and, in order to ensure a cost-efficient yet irreversible pathway towards decarbonisation, CCS and CCU need to be deployed and tested at scale by 2030.

CONTACT DETAILS

The renewed interest for CCS and CCU as a cost-effective technology for large-scale decarbonisation in industry and power reinvigorates the positive momentum seen at a European and national level, with announcements such as the Longship project and funding awarded through the Connecting Europe Facility for Energy (CEF) programme to European CCS and CCU projects (Porthos, Athos, Antwerp CO₂, Acorn Sapling, Ervia).

To support these recent positive developments, existing barriers for the large-scale deployment and development of CCS and CCU need to be tackled. The European Union's increased climate ambition represents a prime opportunity to revise some key pieces of legislation in order to enable the take-off of CCS and CCU projects and to introduce incentives for the technologies. R&I activities will help address current technical challenges along the value-chain, and in this respect, continued support for R&I activities at lower and higher TRL levels is crucial to reduce the costs of the technologies and improve efficiency.

Social acceptance challenges still remain and will require the action of a wide group of societal stakeholders to be addressed. Local administrators, NGOs, academia, and other economic stakeholders play a central role in increasing the awareness around CCS and CCU and facilitating an informed debate around it.

To conclude, CCS and CCU can support the EU's decarbonisation pathway, delivering climate change mitigation and circularity, carbon dioxide removals and early, large-scale volumes of clean hydrogen for industry and homes. CCS and CCU can deliver clean economic growth, safeguarding industrial manufacturing, preserving existing jobs while creating new ones.

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 842214
